

3D Mod Setup Guide

Installing ReShade, then three full-resolution stereo paths: SuperDepth3D + VR-Export, Geo3D + 3DToElse, and geo-11.

This is a streamlined, click-through reference. Start with ReShade, then jump to whichever stereo path suits your display or headset. Every section ends with direct links to the tools it uses. **All of these are single-player only** — never use them on anti-cheat multiplayer.

Step 0 · Install ReShade (add-on build)

ReShade is the host every path below loads inside. You must use the build **with full add-on support**.

1. Download ReShade [from reshade.me](https://reshade.me) and run the installer.
2. Click **Browse**, pick the game's `.exe`, and choose its rendering API. ReShade installs the right proxy DLL: `dxgi.dll` for DX10/11/12, `d3d9.dll` for DX9, `opengl32.dll` for OpenGL, or the global layer for Vulkan.
3. When asked, install the standard **shader collection** (or skip and add only the shaders you need).
4. Launch the game and press **Home** to open the ReShade overlay.
5. For any depth-based 3D, open the **DEPTH** tab and pick the correct depth buffer. If the preview is flat, reversed, or black, toggle `Copy depth buffer before clears` and the `reverse` option until geometry looks right.

ReShade loads through a proxy DLL named for the game's API, then hosts the shaders and add-ons the next sections use.

SECTION 1

SuperDepth3D + SuperVRExport -> full-resolution SBS

Depth-based stereo that works on almost any DX9/10/11 game. The add-on does the full-resolution work for you — **just install the three pieces** and you get full-SBS, no manual preprocessor edits.

1. Install the ReShade add-on build (Step 0).
2. Get [Depth3D](#) and copy SuperDepth3D.fx (and Overwatch.fxh) into reshade-shaders\Shaders.
3. Drop the [SuperVRExport](#) add-on (supervrexport.addon64) next to the game's .exe. It **auto-configures SuperDepth3D for full-resolution SBS** — the full-res settings are applied for you.
4. Start your VR viewer ([Osiris VR Viewer](#)) **first**, then launch the game — the add-on publishes **full-res SBS** straight to it.
5. *Optional:* in the overlay, tune Divergence (depth) and Zero_Parallax_Distance (convergence) to taste, and set the depth buffer in the **DEPTH** tab if 3D looks flat or reversed.

That's it — ReShade + SuperDepth3D + the add-on. No manual EX_DLP / DoubleBuffer edits needed.

SECTION 2

Geo3D + 3DToElse + GeoVRExport -> full-resolution SBS

Real **geometry** 3D (true stereo rendered from the game's geometry) running as a ReShade add-on, then converted to full-SBS for VR. Heavier than depth-based, but more correct depth.

1. Install the ReShade add-on build (Step 0).
2. Install [Geo3D \(Flugan\)](#) — it loads as a ReShade add-on and adds 3DToElse.fx.
3. Place the [GeoVRExport](#) add-on next to the game's .exe — this is what outputs **full-res SBS to the Osiris viewer**.

4. Geo3D's stereo lives in the [Geo3D] block of `ReShade.ini`: tune `StereoConvergence`, `StereoSeparation` and `StereoScreenSize`.
5. Route the output through `3DToElse.fx`: `Stereoscopic_Mode_Input` = Frame Sequential -> `Stereoscopic_Mode` = Side by Side -> `VRExport_Mode` = 1, which feeds the GeoVRExport add-on.
6. Start [Osiris VR Viewer](#) **first**, then launch: 3DToElse -> GeoVRExport -> **full-res SBS in Osiris**.

Tip: if performance is tight, Section 1 (depth-based) is lighter; use Geo3D when you want geometrically correct depth.

SECTION 3

geo-11 -> full-resolution SBS + game fixes

A full replacement for NVIDIA 3D Vision on **DX11** — true geometry 3D, works on any GPU (NVIDIA or AMD), highest quality, full resolution per eye. (No DX12.)

geo-11 renders the game in true 3D and sends a Katanga-VR full-resolution SBS stream to the Osiris viewer.

Install

1. Get geo-11 from the [ThreeDeeJay/geo-11 releases](#) and extract the matching x64 / x32 build into the folder where the game's .exe lives.
2. Add the game's community shader fix from the [HelixMod blog](#) (or [DarkStarSword 3d-fixes](#)) into the same folder — it provides `d3dx.ini` and a `ShaderFixes\` folder. If the fix is for 3DMigoto, copy the geo-11 files over it but **keep the fix's own** `d3dx.ini` and set `force_stereo = 2` in it.

Set the full-res SBS output to Osiris

1. Open `d3dxdm.ini` and set `direct_mode = katanga_vr`. This is geo-11's VR output — full resolution per eye, no panel splitting.
2. In `d3dx.ini` [Device] set `upscaling = 0` and run the game at your **native resolution**, so each eye renders at full res.
3. Tune depth with `dm_convergence` and `dm_separation` in `d3dxdm.ini` (many fixes map F1-F4 to convergence presets).
4. Launch the game (let it overwrite the NVIDIA profile if asked), then open [Osiris VR Viewer](#) — geo-11's `katanga_vr` stream appears as **full-res SBS in Osiris**.

Note: when you later update geo-11, never overwrite the fix's `d3dx.ini` or `ShaderFixes` folder.
